

Optical power meter switch is faulty

Overview

If possible, remove and reinstall the optical modules to check whether the fault is rectified. Optical networks rely on precise power balance—too much power can damage receivers or distort signals, while insufficient power can lead to high bit-error rates, degraded OSNR, or even complete link failures. If the fault is caused by incorrect configuration or networking environment, change the configuration or networking environment. The device management or driver software has a bug. Check compatibility between the optical module and switch. Most switch brands have specific compatibility requirements. Customers in the use of optical modules will more or less encounter a variety of failure problems, such as optical module model selection is correct, the use of jumper is correct and some common problems, customers have the ability to judge and have a clear solution, but for some of the use of. If the transmitting power is low (TxPower Low), the local optical transceiver might be faulty, leading to low receiving power at the opposite end.
